Drug-induced hemoparasitism from 6-thioguanine (6-TG) therapy is characterized by the presence of leukocyte and platelet fragments in the patient's blood. This may lead to severe bleeding or life-threatening anemia. Hemoparasitism is a rare but potentially lethal complication. Because of its severity, it is crucial to detect and treat 6-TG hemoparasitism early. However, there is still debate whether or not to transfuse a patient who has clinical evidence of hemoparasitism and/or has a known history of red blood cell transfusion. This uncertainty may lead to life-threatening anemia in a patient who may then require red blood cell transfusion. We have carried out a systematic review of the literature to investigate whether or not a systematic pragmatic intervention to detect and manage these hemoparasitic events is beneficial in those patients with evidence of hemoparasitism. To investigate whether or not a systematic pragmatic intervention to detect and manage hemoparasitic events in 6-TG-treated patients is beneficial. Randomized controlled trials, controlled clinical trials and retrospective studies examining the efficacy of the pragmatic intervention to detect and manage hemoparasitic events in 6-TG-treated patients. The literature search found no randomized controlled trials or controlled clinical trials investigating the efficacy of the pragmatic intervention to detect and manage hemoparasitic events. Therefore, the review was based on a retrospective study in which 20,032 patients were followed over a five-year period. There was a reduction in the prevalence of hemoparasitism over the study period (7.6% vs. 4.9%). This was attributed to the increased compliance with the recommendations for hemoparasitism prophylaxis and the removal of known or suspected 6-TG nephrotoxic compounds from the circulation. The incidence of red blood cell transf 82157476af
